01. Venice Impact Hub

Location Venice, Italy

Venice Impact Hub: The gas tanks area in Dorsoduro towards a NEB transformation

The thesis proposes the creation of an Impact Hub in Venice, in the former Italgas area of Dorsoduro, as an opportunity for urban regeneration according to the principles of the New European Bauhaus (NEB): Beautiful, Sustainable, Together. Impact Hubs are an international network of co-working spaces and incubators for innovators and social entrepreneurs. The project aims to strengthen Venice's vocation as a lived-in and creative city, attracting new residents, businesses, and talent, reversing the trend of depopulation. The thesis is divided into two parts. The first, Compass Learning Cities, developed with other groups, explores the concept of Learning City promoted by UNESCO, highlighting synergies with the NEB and analyzing international case studies. The second part, Venice Impact Hub, presents the concrete project in the gasometer area, identified as strategic for its accessibility and potential. The intervention is based on a careful urban, regulatory, and historical-architectural analysis. The project involves the regeneration of existing buildings, including the two gasometers, and the construction of a new modular, flexible, and sustainable pavilion. The spaces will house offices, conference rooms, co-working areas, training rooms, a library, community gardens, and event spaces. The entire lot will be integrated into a large urban park, designed as a space for socializing and well-being, in dialogue with the buildings. Particular attention is given to energy efficiency and the use of sustainable technologies (solar panels, rainwater harvesting). The project is intended as a replicable model, capable of combining urban regeneration, social innovation and environmental sustainability, restoring the city as an open, productive and inclusive place.

02. La Culla del Jazz

Location Via Salaria Vecchia, Fara in Sabina, Rieti, Italy

"*La culla del Jazz*" project stems from the desire to preserve as much of the pre-existing buildings as possible. The buildings that populate the area present the characteristic features of industrial buildings, and although most of them do not show any particular character or historical architectural value, the choice was to erect them as monuments and give them the right treatment. Another important aspect sought was to change the topography of the area as little as possible, removing land only where strictly necessary. Examples of this strategy are the internal and external seating system of the Auditurium and the car park. The former sits on a former basin for the collection of virgin pomace and sets the seating, as in Greek temples, on the natural inclination of the ground; the latter maintains the pre-existing site and rises above it with a second floor. The buildings that populate the project lot and host the functions are conceived as pavilions that are apparently unconnected and independent but in reality in continuous relationship. For the design, a 2.5 m module was chosen to generate buildings and plot. In addition, the three new buildings are variations of the same theme: module and reinforced concrete, to stand in continuity with the pre-existing building, whose buildings are predominantly made of brick and concrete. In this jazz-focused park, ideal for hosting international events, there are all the services necessary to accommodate visitors as well.

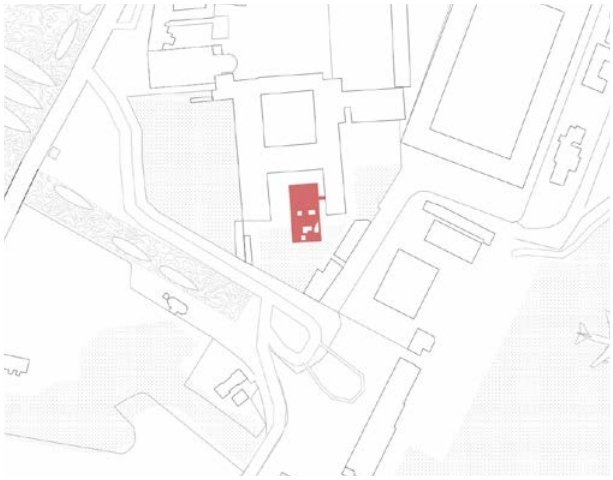
03. Conference hall Global Campus of Human Rights

Location Riviera S. Nicolò 26, Venice, Italy



The project does not just want to propose a building, but aspires to be a symbol, an embodiment of what we think is the Global Campus, the new Global Campus. Inclusion is the principle that unites the three cornerstones of this work: human rights, community, and the neighbouring city of Venice; but it extends its model beyond geographical boundaries and has a universal scope. The firm point in the design was respect for space, a respect that took the form of a work of subtraction aimed at giving space to greenery, the real protagonist of the structure. The trees and greenery present pre-intervention are not affected and the amount of turf is increased through the extension of the park on the roof of the new building. The current structure has a green park with important trees that are unfortunately underused. Combining the latter with the requirements brought by the GC's contact persons, we imagined the pre-existing tree elements as an embodiment of the same rights, creating a true human rights park. Indispensable rights such as the right to life, freedom from slavery, freedom from torture, and the impossibility of retroactivity of prosecution, the new edifice conquers them, includes them, and protects them within its body, allowing them to flourish safely.

04. La casa di Giò

Location Via Luigi Anedda, Parma, Italy

The project “La casa di Giò” was developed as part of a competition organised by the local council to design a gym for wheelchair users. The aim was to develop a distinctive and inclusive architectural design that fully complied with regulatory and functional requirements for users with limited mobility, while keeping costs within the limited budget set for the competition.

The building features a load-bearing structure made of steel profiles and truss beams in the roof, a solution that allows for large spans and creates a spacious, flexible and obstacle-free interior. The interior layout has been designed with linear paths and dimensions that ensure autonomy, safety and ease of use of the spaces, from the changing rooms to the toilets.

The colour scheme reflects the colours of the Parma teams of Polisportiva di Giò, to which the project is dedicated, giving the building a strong identity and a direct link to the local sporting community.

Period 2022.1
Location Borgo Pietro Giordani, Parco di San Paolo, Parma, Italy

The theme addressed is that of the Pavilion, or rather of a temporary structure that would enhance a specific area of Parma. The Cinema San Paolo is structured around the idea of an internal circular space, open towards the sky and surrounded by distribution and service areas. The central space can be used as a conference hall, theatre or open-air cinema, combining the theme of places intended for entertainment and performance in a natural and therefore exceptional dimension. Within the ovoid perimeter is inscribed the circular void. The pavilion relates to the centuries-old pre-existing trees in the park. The reiteration of the slender perimeter piers constitutes a rarefied limit, thus avoiding the use of isolated load-bearing elements. This creates a continuous curtain that encourages a continuous visual dialogue between the interior and the surrounding green space. The structure is designed for the warm months of the year and can be dismantled and stored in the cold months.

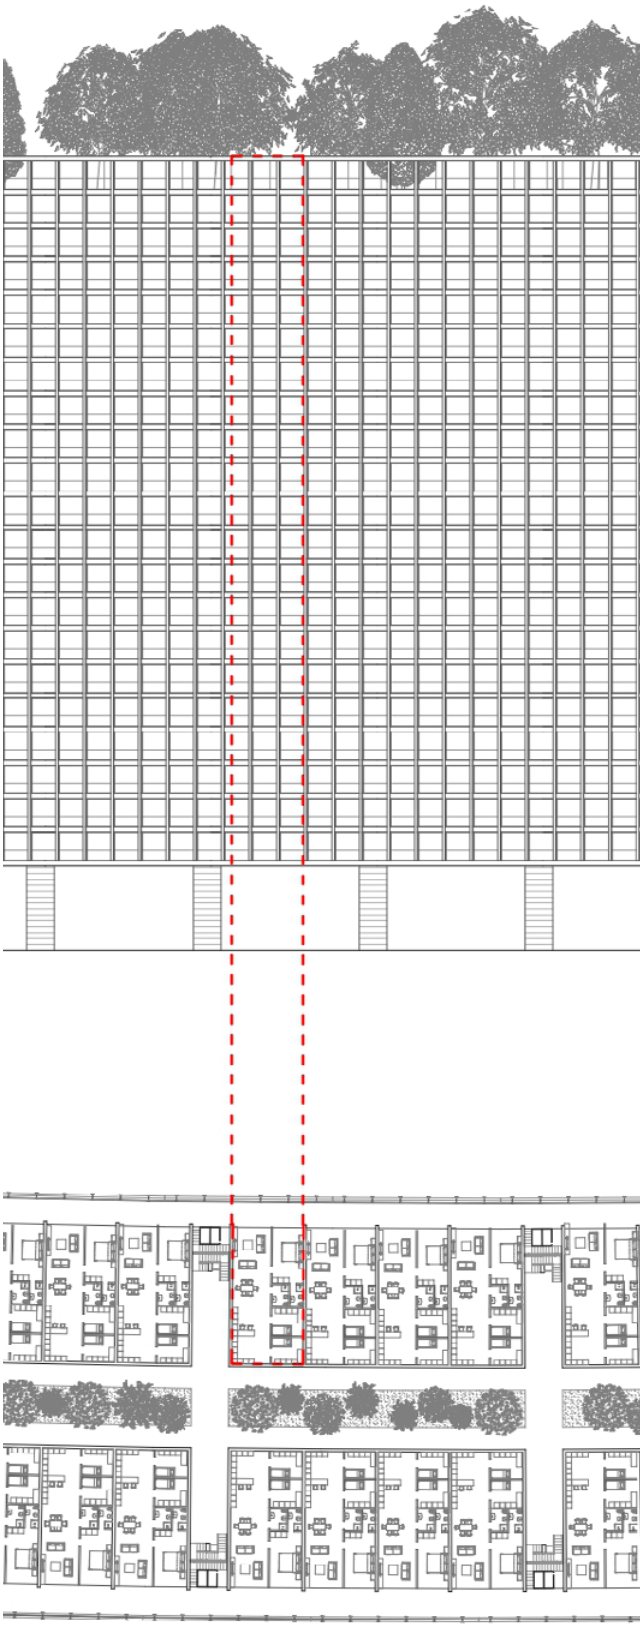
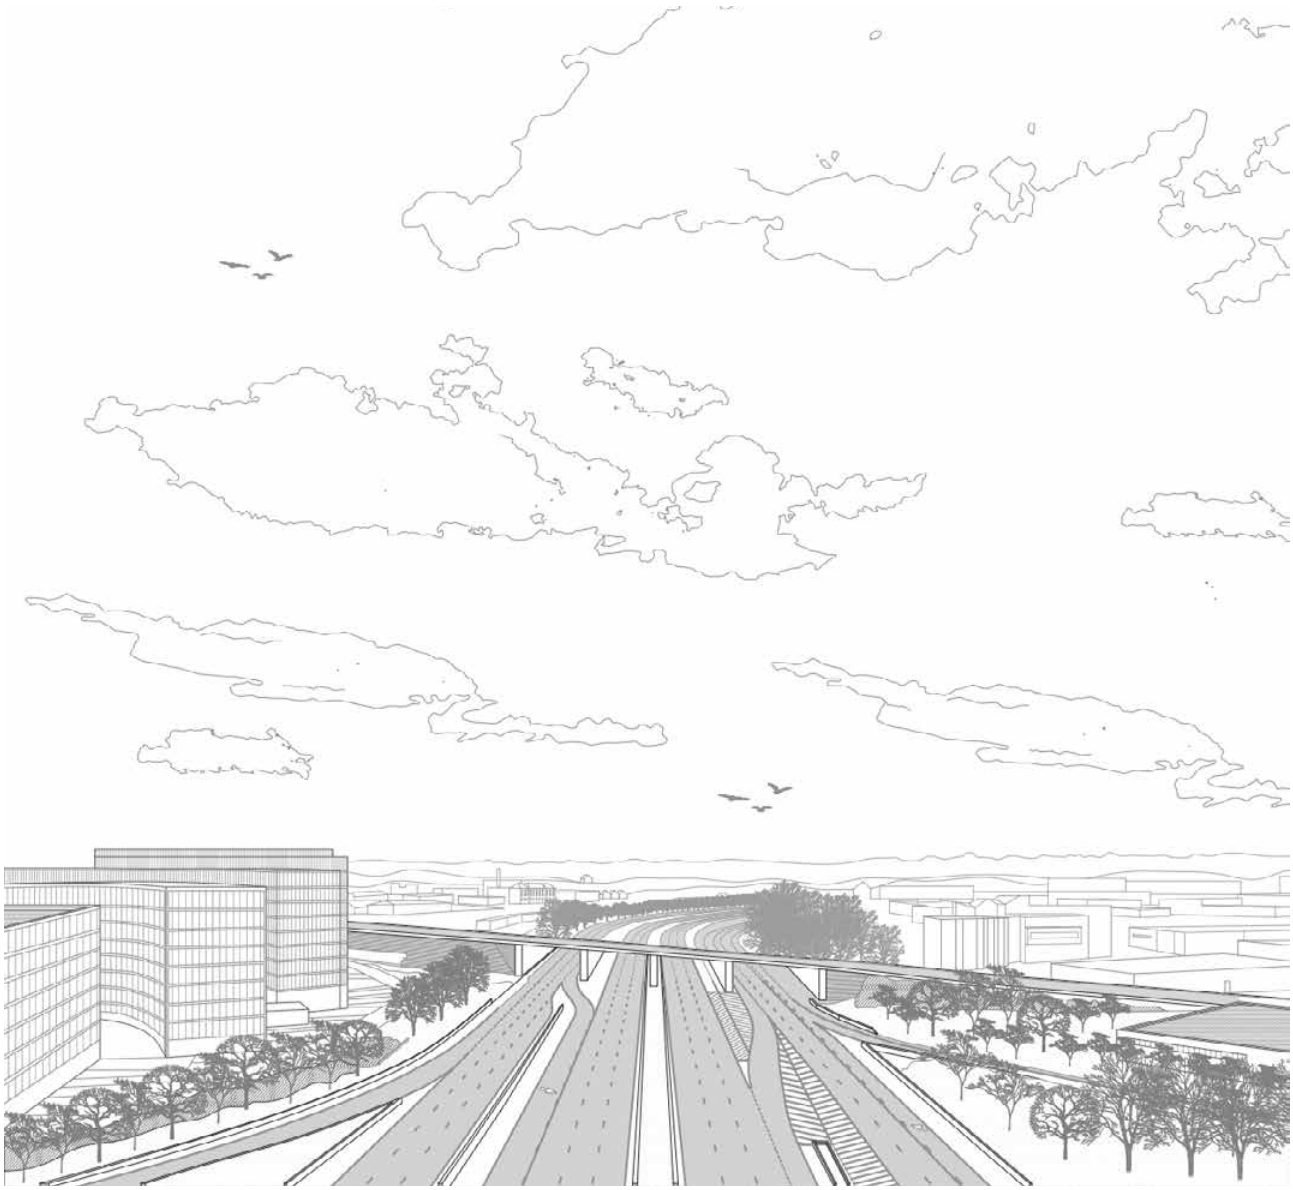
06. Un utopique rémpart pour Bruxelles

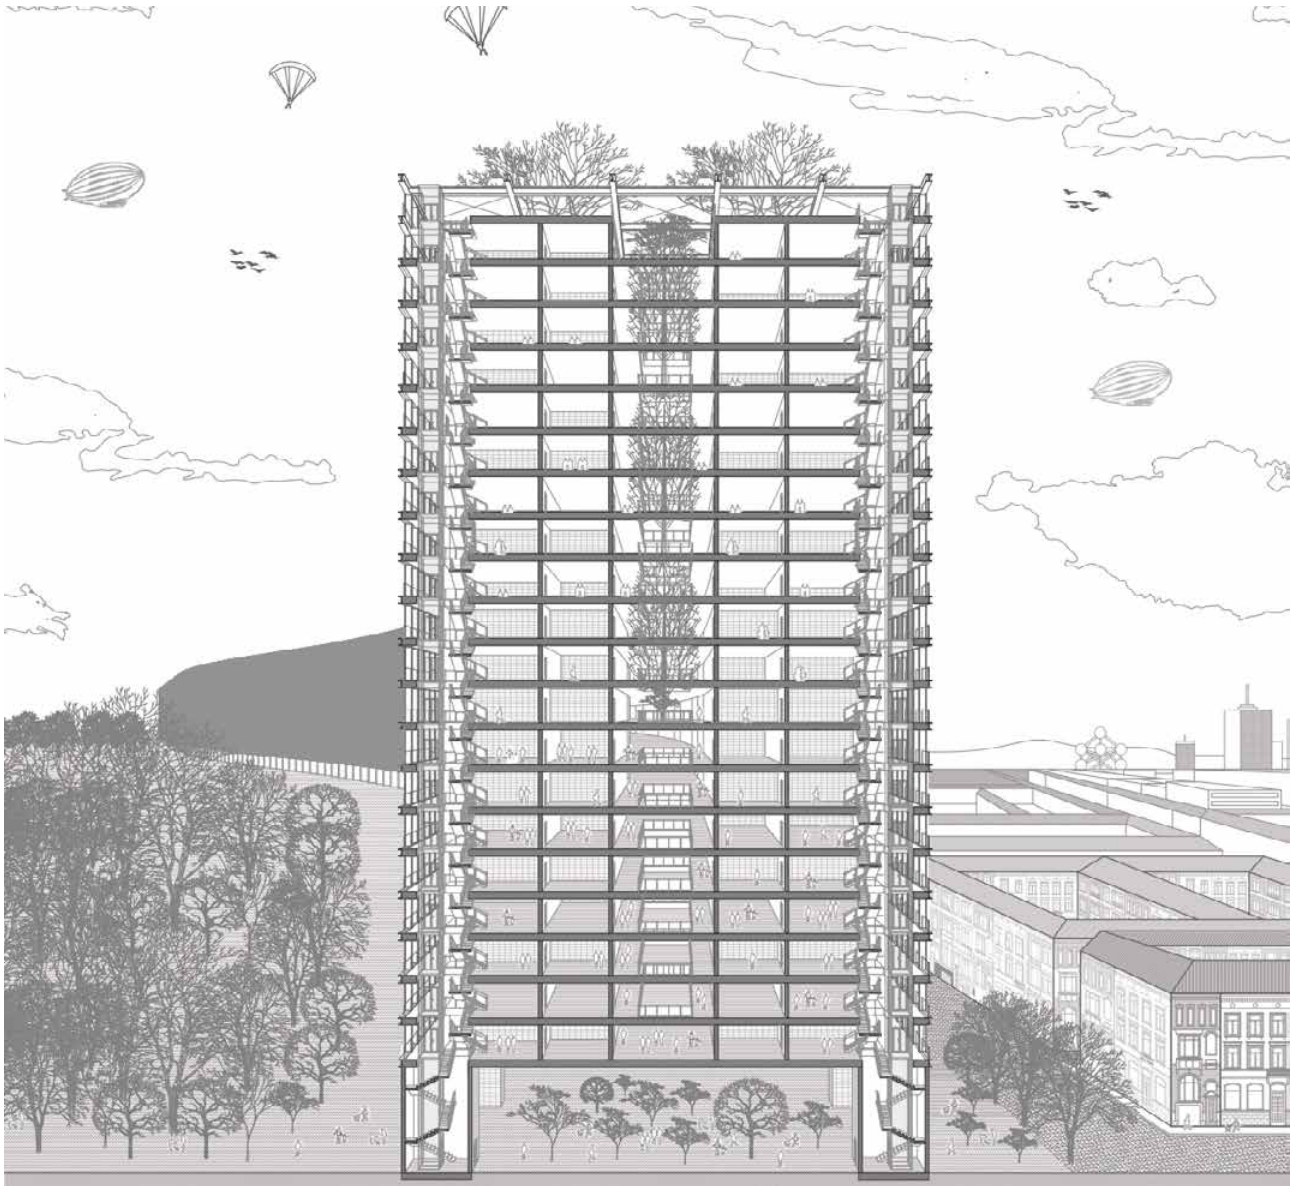
This project aims to provide a solution to a problem that plagues the society and way of life of our times. At first, references were analysed from the father of Utopia, Thomas More, through the socialist utopias of the industrial revolution to current case studies such as The Line in Saudi Arabia. Subsequently analysing the current society, a mother theme was chosen, "*The Artificialisation of Soils*". In fact, more and more, permeable soils are being covered with mineral material that changes their natural characteristics, creating significant problems for ecosystems if uncontrolled. The project seeks to reduce artificialisation by densifying only Belgian cities with more than 100,000 inhabitants. The means to this end is to build *compact cities*. A complementary building will then be constructed in each of the new compact cities that follows the road axis outside the city and can accommodate all the inhabitants who will move into the city from the suburbs and the countryside. This element takes up the ancient idea of the city wall as a shelter. Each compact city will accommodate a number of new inhabitants proportional to the number of inhabitants in the city. Hence, with compact cities it will be possible to limit the artificialisation of land in the Belgian case to 5 per cent, leaving most of the land in its natural state. The illustrated project presents the case for the city of Brussels. The perimeter building that will rise on ring 0 will accommodate 2,000,000 new inhabitants spread over 20 floors.

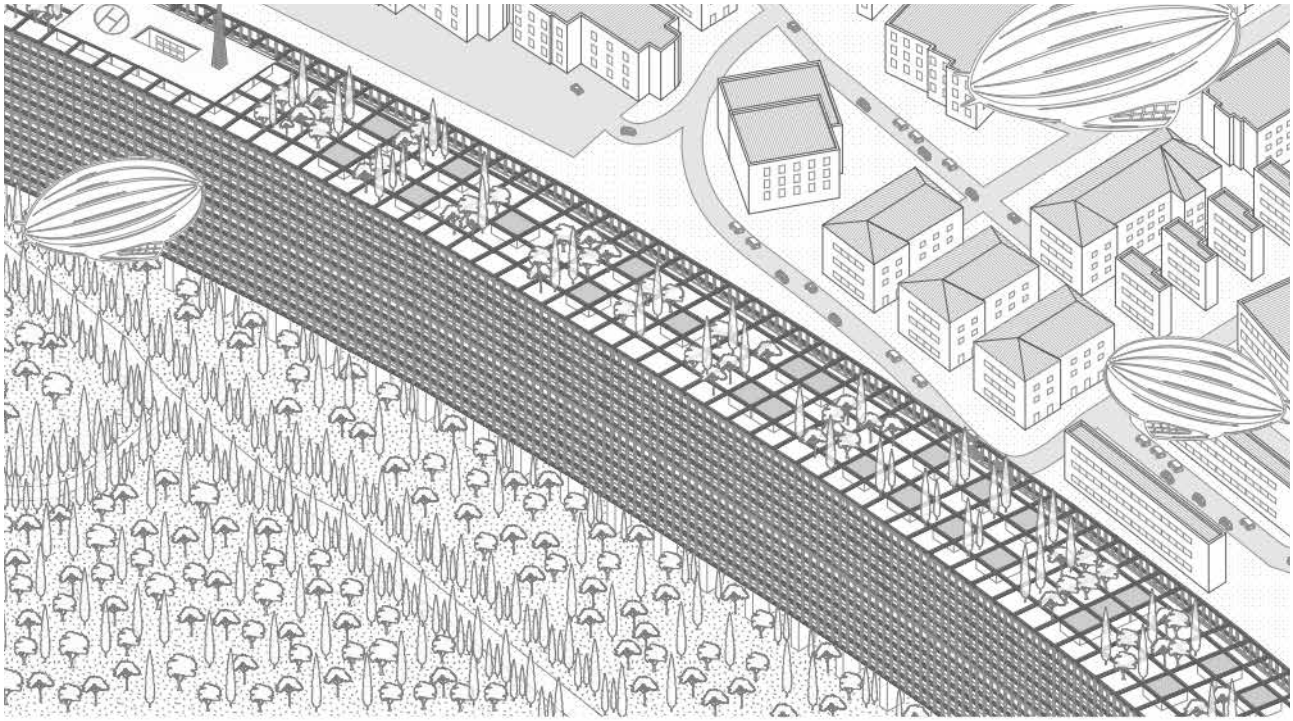
Location Bruxelles, Belgium

Utopias and actuality of living





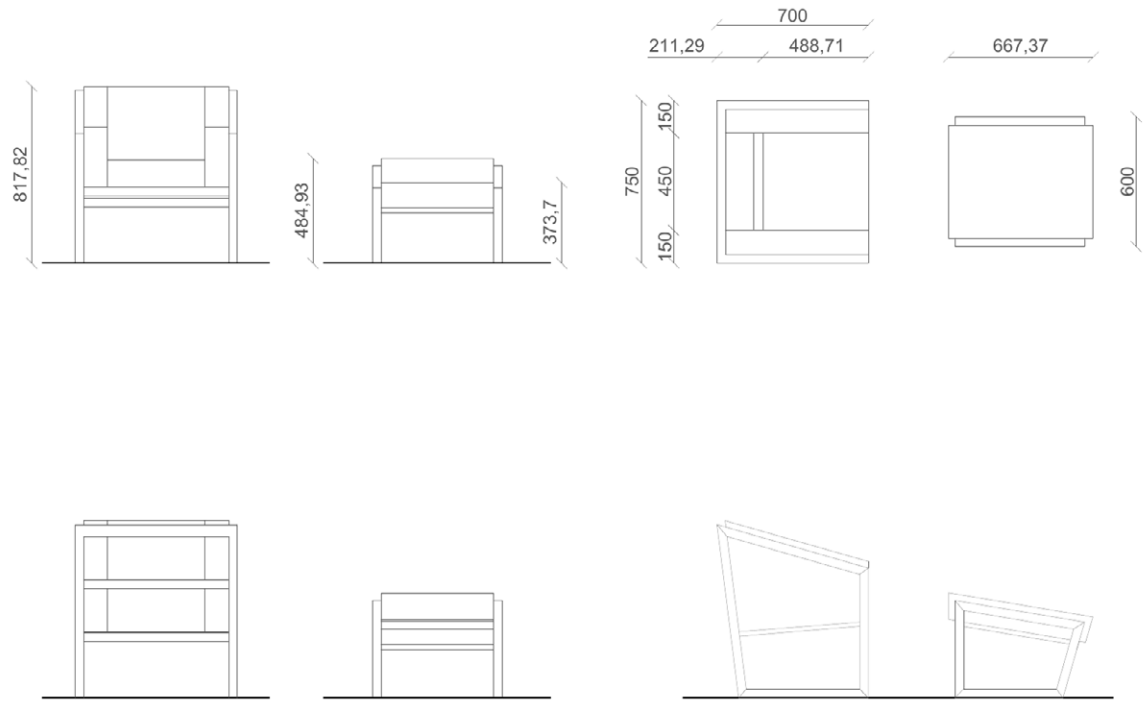




07. Chaise Longue Sharp

The Sharp armchair consists of a structure made of chrome-plated stainless steel square tubing measuring 4x4 cm and 2 mm thick. These metal profiles are welded together. The structure also consists of 2x2 cm, 2 mm thick chrome-plated steel L-shaped profiles that support the sloping seat. Crossed elastic straps are anchored to these profiles to form the seat. The four cushions are removable and filled with goose down with polyurethane foam inserts and covered in synthetic leather in various colours.

The particular trapezoidal shape is dictated by the need to follow the specific positions of the back and arms normally assumed when sitting, seeking to combine them.To increase ergonomics, the seat and backrest are inclined at 5° and 7° respectively.To complement the Sharp Armchair, an ottoman was also designed to reflect the formal research, so it too was inclined to promote the correct posture of the knees.The cushion covers are available in four colours and the structure in three.



08. Chaise Longue Wrap

The Chaise Longue Wrap takes its name from the enveloping effect it creates. It consists of a structure made of chrome-plated stainless steel square tubing measuring 4x4 cm and 2 mm thick. The metal profiles are welded together and to the seat-backrest block, which is 3 mm thick and consists of four modules of stainless steel sheet metal cold-bent in the middle at 10° per side. The modules are then welded at specific angles and covered with a 5 cm thick polyurethane foam insert and synthetic leather upholstery in various colours. The mattress consists of a layer of leather with sloping sides corresponding to the sheet metal and spaced 1 cm apart at the angle changes to allow for proper articulation. Adherence to the structure is ensured by Velcro strips that allow for quick removal.
